#### Abstract

CYRUS D. BANIKAZEMI. The Colors of Prestige: An Analysis of the Forms, Decorations, and Uses of Inca Stone Vessels. (Under the direction of DR. DENNIS OGBURN)

The ethnohistoric and archaeological record provides ample evidence of the ideological significance of metals and pigments in the pre-Columbian Andean world. This study explores the use of these materials in the complex decorative techniques utilized by the Inca when finishing stone vessels. This research integrates data generated from ethnohistoric sources, portable X-Ray Fluorescent (pXRF) tests, and reconstructive experimentation in order to provide a better understanding of how metals and pigments were used by the Inca to signify the elevated status of certain stone vessels. My objective is to show that the decorative processes implemented in the construction of stone vessels can illuminate how these artifacts were used within Inca society.

## ACKNOWLEDGMENTS

I would like to start by thanking my committee for their constant guidance and encouragement: Dr. Ogburn, my committee chair; Dr. Sara Juengst; and Dr. Donna Nash. You all have challenged me in different ways and helped me to become the anthropologist I am today. I am tremendously proud to have been able to learn from every one of you. I am also grateful for the support and reassurance you all have provided me outside of the classroom.

I also want to thank The Field Museum of Natural History for allowing me access to their collections and their equipment. In particular, I would like to thank Dr. Ryan Williams for his help facilitating my visit, Dr. Laure Dussubieux for assisting me with the laboratory facilities, and Christopher Philipp for all of his help with finding the artifacts relevant to this study. Without their support, this project would never have been possible.

In addition, I'd like to state my appreciation for the good people at The University of North Carolina Greensboro. I specifically want to thank Dr. Charles Egeland for his help organizing my trip and for letting me use his lab, Eric Zack for his help while getting me access to the pXRF, and Emily Schach for helping me make last minute preparations.

Finally, I would like to thank all of my friends who have bolstered me during this long process. I especially want to thank Muriel and Thor for always being willing to read over my gibberish. I would also like to thank Curran and Scott for being there when I needed to bounce around ideas, Kyra, Alex and Ratjar for always keeping your house and porch open to me, and Kat, Ross and Trey for being there when I needed to vent. You are all wonderful and I love you all deeply.

## CHAPTER 1: INTRODUCTION

The quality of Inca craftsmanship has consistently astounded the world. Everything from the workmanship of walls to the weaves of woolen textiles has been the subject of scholarly research for centuries. One technology that has been mostly overlooked is the construction and preparation of ceremonial stone vessels. Although it is well known that the Inca decorated stone vessels with elaborately carved motifs, there seems to be a vacuum regarding how the forms and decoration of these vessels reflect their status and possible usage. This has led many past studies to examine stone vessels strictly as functional goods and has meant that there has been little work focused on what these artifacts represented or their ritual use within Inca society. For this reason, I have examined the decorative techniques used by the Inca when producing stone vessels. In this study, I will examine some of the different forms and decorative techniques that the Inca implemented when producing stone vessels and show how this reflects social status, religious significance, and potential usage.

The first part of this study is intended to provide a little background information on the Inca Empire and to highlight some of the material goods they produced that have been understood to reflect complex ideas of identity and prestige. In this part of the study I intend to provide a broad context for understanding the materiality of prestige and ritual in the Inca world as well as to show how some of these same ideas may be reproduced in stone vessels. This will be followed with an overview of some of the work that has focused on stone vessels, an analysis of some of the symbolic motifs that these goods are often associated with, and an examination of some of the additive decorative materials
that are thought to be associated with some stone vessels. These ideas will help form a theoretical backbone for this study that will be continuously revisited.

The next part of this study is dedicated to examining a collection of 30 vessels housed at the Field Museum of Natural History in Chicago, IL. In this section I will first introduce the stone vessels examined in this study and some of the considerations involved with this study. I will then introduce a typology of the studied vessels that will be used for the remainder of this study. This will be followed by a detailed description of how these vessels were studied using portable X-Ray Fluorescence spectrometer (pXRF) analysis as a way to detect for potential elemental concentrations indicative of past surface treatment and will then provide the results of this examination. Finally, I will describe an experiment in which I used a pXRF housed at the University of North Carolina at Greensboro to examine the elemental concentrations of different surface treatments potentially used by the Inca. I do this by measuring the change in key elemental signatures as I apply and remove various surface treatments to basalt stone samples. This is later used as a comparative basis to better understand the readings taken from the vessels at the Field Museum. In sum, I am creating a typology to interpret the studied forms of stone vessels, collecting data relevant to the presence or absence of additive decorative material, and compiling a comparative sample to better interpret how traces of additive decorative materials may be detected post-removal.

The findings of this study will then be considered in the greater context of Inca culture and religion in order to understand how the observed decorative strategies reflect complicated and nuanced ideas of religious practice and prestige. The goal of this study is project is to elucidate how the many styles and decorative strategies displayed in Inca
stone vessels can inform the status and use of these vessels will provide illuminating information on the labor invested during the construction of Inca stone vessels and provide a better understanding of how metals and pigments were used by the Inca to signify the elevated status of certain stone vessels.

## CHAPTER 2: THE INCA AND THEIR MATERIAL CULTURE

2.1 IDENTITY AND PRESTIGE IN THE INCA WORLD

The Inca Empire, also referred to as Tawantinsuyu or "land of the four quarters" by its denizens, reigned from around 1400-1532 C.E. The empire stretched across the Andes mountains and dominated much of the western portion of South America, stretching from its northernmost reaches in Ecuador to its southern boundaries in central Chile (Stanish, 2001). At the navel of the Inca empire was their capital city, Cuzco, which functioned as a ritual epicenter and was home to various buildings of both religious and political significance. While European colonialism ultimately led to the collapse of this state, the efforts of Spanish and indigenous chroniclers has left a wealth of ethnohistoric reports regarding the social, political, and religious practices of the Inca Empire and its people (Murra 1961; Stanish 2001; Bauer and Covey 2002). In conjunction with archaeological findings, these ethnohistoric records can be used to make important inquiries regarding how prestige was materially manifested and displayed. With this in mind, my goal is to illustrate the relationship between high status artifacts and the people that used them by considering how decorative techniques and motifs reflect the function and status of these artifacts. In order to do this, it is first important to examine how status was demonstrated through material objects in the Inca world.

The Inca produced a range of material objects thought to be special, high-value goods intended for elite use. These prestige goods are relevant because they are often culturally imbued with religious, socioeconomic, and/or sociopolitical significance. As Costin notes, items can be interpreted as culturally significant based on: "the rareness and/or inherent value of the materials used to make them, the amount of labor invested in
their production, the symbolic meanings of the materials and design motifs, the social identity of the person(s) who manufactured them, and the social identity of the person(s) who distributed or initially used them" (1998: 125). While strict adherence to these criteria may not be useful when examining all types of prestige goods, Costin (1998) uses them effectively to describe how sociopolitical significance is imbedded in cloth.

Textiles serve as a powerful means of understanding Inca material culture and high-status goods because of their strong association with status and ritual throughout Andean history. When discussing Inca textiles, many past scholars have differentiated the quality of these goods with the categories awasqa and qompi -- Awasqa used to refer to textiles made from coarse wools or cotton thread and constructed with a plain weave, and qompi used to describe decorated and dyed cloth made from high quality wool or cotton (Costin 1998; Femenías 2017). Although these categories have been criticized for being overly simplistic, these terms can be used here in order to talk about Inca textiles in a general sense (Murra 1962; Cobo 1990 [1653]; Costin 1998; Femenías 2017).

Ethnohistoric and modern observations suggest that while awasqa fabrics were used to satisfy various utilitarian functions, qompi blankets, shirts, and other garments were treated with a more sacred reverence (Murra 1962; Cobo 1990 [1653]; Costin 1998). Qompi goods are thought to have been associated with ritual offerings, used to dress religious totems, and worn by elite members of society, including the ruler of the Inca Empire, known as the Sapa Inca. In addition to this, the production of qompi is thought to have been state-controlled, in which the Inca administration carefully recorded the qompi tributes from conquered provinces, and then distributed them among political, religious, and military institutions throughout the empire (Murra 1962; Costin 1998). By
using Costin's (1998) criteria (stated above), we can see that, unlike awasqa, qompi textiles were imbued with important sociopolitical significance, and can be viewed as prestige goods. To treat qompi as simply a type of prestige good is, however, reductive. As numerous scholars have shown [see: Murra 1962; Cobo 1990 [1653]; Costin 1998; Katterman 2002; Phipps 2010; Femenías 2017], the patterns, colors, and weaves of qompi reflect invaluable information regarding the gender, regional identity, and social rank of the person(s) and rites with which the objects are associated. I will show that by examining stone bowls in a similar fashion to how textiles have been studied in the past, it is possible to glean equally rich information from such objects.

Similar to the way that textiles can be used to study sociopolitical identity, we can examine the presentation of prestige by investigating keros. The term kero refers to a type of tall, wooden drinking vessel with flared walls. These vessels were produced in pairs and are thought to have been primarily used for the ritual consumption of chicha (an Andean maize alcohol) throughout Andean prehistory and into the present (Pearlstein et al. 2000; Allen 2002; Kirsop 2013). When studying keros, scholars have noticed a wide variance in styles. In the study "Technical Analyses of Painted Inka and Colonial Qeros" (2000), Ellen Pearlstein and others examined over 150 keros and found that while a some of these vessels were decorated with vibrant paints, the majority were bare of pigments. Of those that were painted, Pearlstein et al. found that the Inca were using an abundance of pigments that were either dangerous to procure, scarce, or otherwise valuable minerals, such as: cinnabar, realgar, pararealgar, orpiment, cerussite, hydro-cerussite, malachite, brochantite (Peterson et al. 2010; Rapp 2009). Pearlstein et al. goes on to note that, "Earth pigments, i.e., those derived from iron compounds, appear only rarely to form
browns" (2000: 99). Considering that earth pigments would have been more accessible, and thus considered less valuable than the pigments Pearlstein et al. most commonly observed, it seems that when the Inca were painting keros, they preferred rare pigments that would have reflected status. This means that the act of painting may have operated as a way of not only decorating but also of increasing the perceived value of the kero, thus transforming a less formal vessel into a more formal vessel. While it should be stated that all keros, regardless of decoration, would have been highly valued as ritual goods, the use of pigments would have been an important way to add both color and prestige to a good.

### 2.2 DECORATIVE TECHNIQUES AND SYMBOLISM

The way in which stone was perceived by the ancient Andean people presents a crucial consideration when studying the symbolic significance of Inca stone vessels. While it is undoubtedly true that most stone tools served primarily utilitarian functions and did not possess a greater symbolic meaning, the potential religious significance of a stone artifact is amplified when these goods were fashioned from an uncommon type of stone or was quarried from a religiously noteworthy locale (Ogburn 2004; Dean 2010; Fortin 2015). This is because stone and stone artifacts were capable of being an incredibly important religious and symbolic material to the Inca peoples. As Kevin Vaughn and Nicholas Tripcevich note regarding the pre-Hispanic peoples of the Andes, "The power inherent in material from the earth to simultaneously contain physical presence, social linkages to places where mining occurs, and sacred power derived from an animated landscape brings the materiality of mined substances to foreground in many of these studies" (2013: 9). In this way, stone goods forged a profound connection between the physical and spiritual worlds for the Andean peoples, and thus suggests that
some stone vessels may have been considered innately sacred based on the material from which they were constructed (Cobo 1990 [1653]; Garcilaso de la Vega 2006 [1609]; Dean 2010; Bray 2013; Fortin 2015).

One of the most detailed treatments of stone artifacts that I have been able to find comes from Burger and Salazar's work Machu Picchu: Unveiling the Mystery of the Incas (2004). While this publication does an exquisite job at detailing the forms, carved iconography, and dimensions of the vessels catalogued, it makes little attempt to distinguish vessel types or interpret how the Inca people used these vessels and, as a result, simplifies the range of artifact types it includes. Despite this perceived lack of nuance, Burger and Salazar (2004) detail a range of stone vessels that encompasses both utilitarian and prestige goods. This work has thus served as an invaluable asset for both developing my typology and understanding how the Inca used these goods.

Burger and Salazar (2004) describe a range of stone vessels, some of which were decorated and some not. Of those that were decorated, a common motif observed was snakes and felines. While it is often difficult, if not impossible, to discern the exact meanings of all iconographic and symbolic depictions, it is necessary to recognize how recurring themes may reflect the culture in which they are found. Thus, here I provide a general overview of the cultural significance of these motifs, which will later be discussed in the specific contexts in which they are found.

Chroniclers such as Father Bernabe Cobo (1990 [1653]), Garcilaso de la Vega (2006 [1609]) and Cristóbal de Molina (2011 [16 ${ }^{\text {th }}$ cent.) all report the cultural and religious relevance of these animals within the Inca world. In particular, the waving form in which snake motifs are commonly represented throughout Andean cultures has led
some scholars to propose that this imagery is in some way representative of the flowing nature of liquid (Allen 2002; Burger and Salazar 2004). This association between snakes and water has also been noted by chroniclers such as Father Barnabe Cobo, who states:

However, what I think is that by saying that a serpent encircled the whole island, they meant, and it should mean, the water of the island, and on clear days the rays of the sun shimmer on the water is such a way that from the beach the waves seem like painted snakes of various different colors. (1990 [1653]: 98)

This marriage between water and serpent iconography is further exemplified when looking at a type of vessel known as a paccha. The word "paccha" translates from Quichuan to "correr el agua" (Joyce 1922: 145) or "running water," and refers to "any vessel designed so that liquid poured in one end circulates through the vessel and flows out an opening at the other end" (Allen 2002: 182). People likely drank from these vessels by pouring a liquid into a bowl-shaped basin that would drain into either a zig-zag or double zig-zag channel running through a "plank" and then be poured into one's mouth (Joyce 1922; Joyce 1924; Allen 2002). Not only are the pacchas commonly adorned with snake iconography, but it is possible that the channels themselves resemble and represent the sinuous form in which snake motifs have most commonly been represented throughout Andean culture (Allen 2002).

Like serpents, feline imagery was culturally significant to the peoples of the Inca Empire, and is thought to have been an important symbol of power (Cobo 1990 [1653]; Allen 2002; Burger et al. 2004; Garcilaso de la Vega 2006 [1609]). This symbolic association between felines and power is supported by Garcilaso de la Vega, who states,
"...For this reason they call this entry of the stream and the street the gate of sanctuary while the place where the stream left the city was called 'the lion's tail,' indicating that [Cuzco] was sacred... and a lion in their arms and warfare" (2006 [1609]: 68). Scholars have shown that Cuzco was both the administrative and religious epicenter of the Inca empire and that the city itself was perceived as a symbol of the authority of the Inca empire (Ogburn 2004; Besom 2010). By claiming that Cuzco was "a lion in their arms and warfare," Garcilaso de la Vega is not only describing the city's military and political importance, but he is also inadvertently characterizing the lion as a symbol of these qualities.

In addition to carved motifs, the status and use of stone bowls may be reflected by certain surface treatments, specifically surface treatments involving pigments or metals. The term "pigment" is defined as an insoluble, organic or inorganic, natural or artificial colorant that is suspended in a medium such as natural resin, glue, animal tallow, blood, casein, eggs, urine, oil, wax, or human saliva (Rapp 2009). It is beneficial to differentiate pigments from dyes, as dyes, by definition, are soluble organic colorants that are incapable of imparting color into paints alone, though they can be retained by a pigment in order to produce what is called a 'lake' (Rapp 2009). Over the course of this study, I will focus specifically on "mineral pigments", or inorganic pigments that have been geologically sourced. This is because most mineral pigments are resistant to decay, detectable through pXRF analysis, and were commonly used throughout the Andes. In order to produce a rich range of colors and finishes, the Inca exploited various oxides, hydroxides, and carbonates of copper, iron, and manganese as well as clays and other
natural earth substances in order to produce vibrant mineral pigments (Rapp 2009; Peterson 2010; Siracusano 2011; Sepúlveda et al. 2013).

The Inca collected mineral pigments in high volume by maintaining dedicated mining operations. Much like resources that were selected to be used for lapidary or metal production, some pigments were considered a high status good and were specifically targeted for procurement (Rapp 2009; Sepúlveda et al. 2013; Peterson 2013). While pigments were sought out independently of ore, it is important to note that ores and mineral pigments often occur in geologic tandem. For example, the pigments malachite $\left(\mathrm{CuCO}_{3} \cdot \mathrm{Cu}(\mathrm{OH})_{2}\right)$ and azurite $\left(2 \mathrm{CuCO}_{3} \cdot \mathrm{Cu}(\mathrm{OH})_{2}\right)$ were exploited alongside copper ore, and, similarly, cinnabar (HgS) was commonly found in relation to silver ore (Rapp 2009; Cooke et al. 2011; Peterson 2013). Mineral pigments were often used to decorate high status goods and could have been used as means to demonstrate the religious significance of certain goods. This is because of the ability for pigments to bestow color onto a person or object.

Colors are reported to have had important symbolic attachments in the Inca world. Not only would specific colors have been used to represent certain deities, but the use of colors and colored objects may have been a way to direct offerings to particular gods. This is reported by Father Cobo when he describes a ceremony involving animal sacrifice,

Each one of the Gods was assigned certain of these animals according to color and markings. Brown sheep of the color of guanacos were sacrificed to Viracocha; white ones to the Sun, and of these, the smooth-furred were sacrificed for certain purposes with different ceremonies... In the city of Cuzco, a smooth-furred sheep was sacrificed to the Sun every day. This
animal was dressed in a red vest before it was burnt. This was the Sun's offering. (1990 [1653]: 113)

Specific pigments of certain colors were likely used for similar religious purposes. If these pigments were used to draw specific connections to deities, it seems likely that treated as an important religious material independently of the goods they were used to decorate.

Not only would pigments have been religiously important, the act of procuring them would have been labor intensive. Ethnohistoric and archaeological findings show that the Inca constructed mines exclusively for the procurement of pigments such as cinnabar (Garcilaso de la Vega 2006[1609]; Suarez 2016). Even with dedicated mines, the availability of some pigments still seem to have been societally limited. Garcilaso de la Vega notes:

As the Indians became so attached to the color ichma (cinnabar)... that they would go to all lengths to get it, the Inca feared they would come to harm in caverns and prohibited its use by the common people, restricting it only to women of the royal bloodline... The pallas (women of royal blood) used no other cosmetics but powered ichma, and that not every day but only occasionally on feast days... The color ichma was used sparingly as I have mentioned in order to spare the vassals the danger of mining. (2006 [1609]: 79)

While aspects of this account are intended to justify the restriction of cinnabar to the elite class, there is likely truth to Garcilaso de la Vega's observation regarding the hazards of mining. This is because of the way that some minerals form in tandem. Even in situations where the intended resource being mined is not toxic itself, the miner may still be risking
exposure to other potential geological toxins (Rapp 2009; Peterson 2010). The limited social accessibility of certain pigments is likely due to a combination of factors including: the labor cost involved with general mining, the potential dangers associated with mining toxic pigments, and the general scarcity of minerals of this type (Peterson 2010). Rare and difficult to obtain pigments would have been more accessible to the Inca nobility and are more likely to have been used for elite purposes.

Though metal gilding and painting are two radically different processes, it is conceivable that these two procedures may have been undertaken for similar purposes. This is because of the unique way in which metal was perceived in the Andes. As Heather Lechtman notices:

Color was the single property of metal, whose achievement and manipulation stimulated the most innovative and sophisticated developments of the technology... In Europe and the Near East the manufacture of bronze and iron tools of war, agricultural tools, and wheeled conveyances provided avenues of utility enabling the metallurgical revolutions of the Bronze and Iron ages. In the Andes, the locus of attention of the metallurgy is not to be found in the realm of utility but in the realm of the symbolic. Thus, Andean metallurgy received its greatest stimulus in the arena dominated by status and political display, and the objects that carried such normative power lay squarely within the aesthetic locus of Andean societies... (1994: 5-6)

What this means is that while the Inca made use of metal for pragmatic purposes, a main driver for metallurgic development was the pursuit of new and unique colors. This close association between metallurgical development and color was also noticed by researchers such as Scott (2011) and Siracusano (2011) who both note the inseparable nature of metallurgic technologies and color production in the Andean world. While metals were a more versatile material, both materials fulfilled a similar symbolic role as both were
sought and processed for the purpose of producing meaning through color (Letchmen 1994; Scott 2011; Siracusano 2011).

Though metal gilding and painting are two radically different processes, it is conceivable that these two procedures may have been undertaken for similar purposes. This is because of the unique way in which metal was perceived in the Andes. As Heather Lechtman notices:

Color was the single property of metal, whose achievement and manipulation stimulated the most innovative and sophisticated developments of the technology... In Europe and the Near East the manufacture of bronze and iron tools of war, agricultural tools, and wheeled conveyances provided avenues of utility enabling the metallurgical revolutions of the Bronze and Iron ages. In the Andes, the locus of attention of the metallurgy is not to be found in the realm of utility but in the realm of the symbolic. Thus, Andean metallurgy received its greatest stimulus in the arena dominated by status and political display, and the objects that carried such normative power lay squarely within the aesthetic locus of Andean societies... (1994: 5-6)

What this means is that while the Inca made use of metal for pragmatic purposes, a main driver for metallurgic development was the pursuit of new and unique colors. This close association linking metallurgical development to color is also noticed by researchers such as $\operatorname{Scott}$ (2011) and Siracusano (2011) who both note the inseparable nature between metallurgic technologies and color production in the Andean world. While metals were a more versatile material, both materials fulfilled a similar symbolic role as both were sought and processed for the purpose of producing meaning through color.

Not only were both of these metals and pigments rare or otherwise difficult to obtain, but they were perceived by the Inca as unique materials that were capable of
endowing social and religious significance through color. The use of these materials when decorating stone vessels would have not just been a way to make the good more visually striking, but also a way of endowing ritual significance to it in a way that would increase its perceived value and prestige. While it may be difficult to ascertain the exact symbolic associations of this type of expression, we can begin to appreciate this type of expression by examining stone vessels in a holistic manner.

## CHAPTER 3: ANALYSIS

### 3.1 SAMPLE

This research project was designed to examine Inca stone vessels in a holistic manner that encompasses form, decorative motifs, and potential surface treatments achieved through the use of pigments and metals. For this study, I examined a sample of 30 Inca stone vessels housed at the Field Museum of Natural History. All vessels examined in this study are thought to be Inca, however, I did not acquire detailed provenience information regarding any of these vessels. Because of the antiquity of the collection and ambiguities involved with the donation process, it is likely that any existing provenience information regarding these vessels is misleading. This means that it is likely that some of the vessels I am calling Inca in this study may not actually be Inca in origin. While this incertitude may problematize aspects of this analysis, the key ideas this study addresses regarding religious practice and the presentation of prestige are not specific to the Inca and are likely to still apply.

Due to limitations of time and resources, the collection studied does not represent the total collection of stone vessels housed in the museum, but rather a sample that is meant to encapsulate the relationship between stone vessels and decorative strategies. While some of these vessels show visible signs of decoration, such as carved motifs or preserved exterior pigmentation, other vessels seemed more utilitarian in design. The range of vessel types selected is meant to represent a range of forms, ornamentations, and potential uses. Of the artifacts studied, all are thought to have served more than a purely aesthetic function and were likely used to contain things -- either liquids or solids, though specifics are yet to be determined. In this section, I first present a typology to characterize
the specific type of stone vessel being analyzed, then evaluated the chemical signatures from the interior and exterior of the selected vessels, as measured through use of pXRF , and finally, compared these signatures with the signatures generated through experimental decorative reconstructions. Throughout this study, I refer to specific vessels by the artifact number assigned by the Field Museum.

### 3.2 TYPOLOGY

To my knowledge, a detailed typology of Inca stone vessels has yet to be formalized, careful treatment has been given to establishing this typology in order to create a comparative basis with which to examine how vessels may vary based on decorative strategy. The forms of these vessels are characterized based on structural qualities such as size, shape, interior depth, interior surface type, and presence/absence of handles. Based on these criteria, I have defined six distinct types pertinent to this study: Cocha, mini-cocha/cocha-like, handled-bowl, teacup mortar, stationary mortar, and miscellaneous. In addition to form, I have noted the use of exotic, multi-colored stone that may reflect distinctive cultural significance (Table 1).

Of the thirty samples, five vessels have been identified "cochas" (A2246, A3225 A3256, A3271, and A3325). I have identified cochas as large, circular vessel with a shallow basin, flat interior surface, a vertical rim and flat bottom. While this vessel type is often accompanied by handles and exterior carved motifs, there is sufficient stylistic variation to assume that these characteristics are not a defining quality. This is most clear when comparing the shapes and styles of the vessels to each other. As seen in Figure 1, these vessels all share the same rudimentary form and approximate size, however, the
presence of handles and carved iconography is variable. Of the three vessels that did have handles (A2246, A3271, and A3256), all had two looped handles on opposing sides. Although past researches have referenced these vessels as mortars (Burger and Salazar 2004), their definitive flat interior surfaces and horizontal lip would likely present a surface difficult to use for grinding. Interestingly, A3271 and A3225 are both decorated with carved iconography and are both made from exotic, multi-colored stone. This will be revisited in the discussion section of this paper. It is worth noting that although these vessels appear to be similar to those reported from Machu Pichu by Burger (2004), none of these vessels show any evidence of fracture on the distal surface that might be indicative of a previous mounting or pedestaling.

Two vessels have been identified as "mini-cocha/cocha-like" (A3274 and A3324). As seen in Figure 2, both of these artifacts have the same circular shape, shallow basin, flat interior surface, and flat bottom as the cochas examined, but are considerably smaller, measuring less than 15 cm in diameter and 7.5 cm in height. Neither vessel displayed any carved iconography. Vessel A3324 had two intact looped handles on either side of the vessel, while A3274 had two fracture scars on one side, indicating the past presence of a single looped handle. In addition to only having had a single looped handle, A3274 has an atypical convex exterior surface.

Six vessels have been identified as "handled-bowls" (A3229, A3233, A3238, A3259 A3301, and A3309). These vessels have been defined by: large bodies, bowl-like exterior shape, concave interior surface, and the presence of one or more handle. As displayed in Figure 3, all vessels of this type display some type of exterior surface treatment, either in the form of carved iconography or an additive surface treatment. A

3229, A3233, A3238, and A3301 prominently display feline imagery incorporated into the handles of the vessels. In addition, A3233 and A3238 also display serpents zigzagging vertically along the base of the bowl. The only vessels to not incorporate any feline iconography were A3259 and A3309, lack carved designs. Instead, A3259 was made from an exotic, multi-colored material and seemed to be finished with a semireflective clear coat preserved along the top portion of the vessel. Similarly, A3309 displays signs of a surface treatment on a single spot along the exterior profile of the vessel (Figure 7). This area preserved brownish red, yellow, and black pigments, indicating that the vessel may have had a patterned exterior in the past. The only other vessel to display any visible pigment is A3238, which had the remains of a bright red pigment preserved between the carved serpent imagery.

Nine vessels have been identified as "teacup mortars" (A2211, A3276, A3277, A3294, A3300, A3310, A3328, A3329, and A3346). Vessels of this type are small enough to comfortably fit in one's palm, have confining concaved interior surfaces, and exhibit signs of post-production grinding and/or pulverizing. As presented in Figure 4, there is some morphologic variation amongst this category. In particular, vessels A2111 and A3328 have straighter exteriors and flat, well-defined distal surfaces that allow the vessels to rest without spilling. The other vessels all displayed a dome shaped exterior with a slight, if not entirely nonexistent, resting surface. Furthermore, of this type, A3328 is the only vessel to have a handle. Given the size and general shape of these mortars, I believe all of them were meant to be held while in use. The reason behind these morphological variations may have to do with the specific type of material each vessel was intended to be used to process or may be the result of regional typological variation.

Many of these vessels seem to have stain marks lingering in their interior bowls, which are assumed to be the remnants of the material processed in these mortars or some type of lubricant used to ease the grinding. In the case of A3294, the stains found were a distinctive blue color, leading me to believe that this vessel may have been used during the production of a valuable pigment, such as azurite. Aside from the handle associated with A3228, none of these vessels have any signs of carved or painted ornamentation.

One vessel, A3278, has been identified as a "semi-stationary mortar". This vessel is comparatively large bodied, with a disc shaped exterior and a deep concaved interior. The interior shows signs of post-production grinding and pulverizing (Figure 5). Notably, this particular vessel has a hole located in the middle of the interior bowl, which may be the result of aggressive use, a ritual in which the vessel was "killed", or clumsy excavation, transportation, and/or storage practices. Unlike the teacup mortars discussed above, the stationary mortar is large with a solid flat bottom. Although A3278 was not so big that it could not be easily moved, this vessel would have likely remained stationary when it was in use.

I have categorized seven vessels as miscellaneous type (A3247, A3254, A3289 A3323, A4187, A4157, and A4252). Both A3323 and A4187 are palm-sized shallow disc-shaped tools with no discernable resting surface and only a slight lip to demarcate the interior of the vessel from the mouth. While A4187 has visible staining on the interior, it remains unclear whether these vessels were used in a manner similar to the tea cup mortars, or if they served some other purpose.

Artifacts A3254 and A4252 are interesting as they are both extremely large, roughly rectangular vessels with thick, distinct lips. The interior surface of both vessels is
slightly bowled, and there is clear evidence of grinding, pounding and staining. While both vessels are somewhat similar to batáns, (a common style of large grind stones used to process foods) the steep, well-defined walls of these vessels are uncharacteristic of most examples seen. This may indicate that these grinding tools are separate from classic batanes.

Artifacts A3289, and A4157 are perhaps the most perplexing stone vessels examined in this study. A3289 and A4157 are both rectangular stone vessels with shallow rectangular basins and mostly flat interior surfaces. Interestingly, both vessels have a single notched opening along the top of one of the walls of the vessel that seems to be intentionally designed (Figure 6). A3284, which is particularly well-crafted and finely polished, has this opening along one of the smaller sides of the rectangle while A4157 has this opening along one of the longer side of the rectangle.

### 3.3 PXRF LAB ANALYSIS

For this portion of the study, I used pXRF spectrometry as a tool for detecting and analyzing the inorganic trace residues left over from decorative surface treatments that may no longer be visible. This tool allows me to circumvent many of the innate limitations and difficulties involved with visual analysis and identification. This is because many of the visual qualities of mineral pigments, such as vividness (the hue of the colorant), hiding power/opacity (a pigment's ability to obscure the covered surface), and permanence/light-fastness (a pigment's resistance to fading from photochemical deterioration) are subject to change based on the type of pigment, the quality of the artifact's initial preservation, and the conditions in which the artifact has been
subsequently stored (Rapp, 2009). These factors may also lead a once pigmented artifact to no longer express any visual presence of coloration. This problem closely echoes difficulties when trying to determine if an object was once adorned in metal. By coupling potential optical cues with chemical data, it is possible to more accurately ascertain if an object received any type of surface treatment.

PXRF serves as an efficient and cost-effective tool to use for this mode of analysis. Some of the most notable advantages of using XRF are that it is non-destructive, comparatively inexpensive, relatively quick - gathering reliable results in as few as $11 / 2$ 2 minutes - and easy to use, as it requires minimal preparation of both the equipment and samples (Shackley 2011; Shackley 2012). Despite these advantages, there are certain innate limitations to XRF analysis that deserve consideration for this study. PXRF analysis is most accurate when analyzing samples that are $>2 \mathrm{~mm}$ thick and that completely cover the sensor, which is around 10 mm in diameter. This means that the instrument will primarily be reading the chemical composition of the object itself, and not just the potential remnants of any pigments or adorned metals. Additionally, when compared to other tools used for spectral analysis, pXRF is more restricted in terms of the number of elements it is capable of detecting. PXRF's ideal detection range is limited to elements between the range of Titanium (Ti) (atomic number 22) to Tin (Sn) (atomic number 50). PXRF is capable of detecting many elements outside of this range, however, the farther the subject element is removed from this range, the less accurate the results become, and the less capable the instrument is at detecting minute concentrations. This is especially true with lighter elements (Shackley 2011; Shackley 2012).

These weaknesses can be addressed by taking multiple readings of each artifact. For most, I took at least 4 readings, which were taken from the interior bowl, the exterior sides, and the bottom. Additional readings were taken of particularly large vessels and specific areas that expressed visible remnants of pigmentation or staining, and fewer readings were taken from particularly small vessels in which the pXRF could not safely make contact with the interior surface. When studying the results, I primarily focused on relevant elements that can be closely associated with specific pigments, all of which tend to be within or near the instrument's ideal precision detection range. These elements include lead $(\mathrm{Pb})$, mercury $(\mathrm{Hg})$, gold $(\mathrm{Au})$, tin $(\mathrm{Sn})$, silver $(\mathrm{Ag})$, arsenic $(\mathrm{As})$, copper $(\mathrm{Cu})$, iron $(\mathrm{Fe})$, zinc $(\mathrm{Zn})$, calcium $(\mathrm{Ca})$, and sulfur $(\mathrm{S})$. The presence, absence, and combination of these elements across the exteriors of the vessels should be sufficient for indicating the past presence of metals and alloys such as gold, silver, copper, bronze, and tumbaga (a copper-silver or copper-gold alloy in which the copper is chemically subtracted from the surface) and pigments such as cinnabar $(\mathrm{HgS})$, realgar $\left(\mathrm{As}_{4} \mathrm{~S}_{4}\right)$ / orpiment ( $\mathrm{As}_{2} \mathrm{~S}_{3}$ ), ochers (iron oxide based), sphalorite ( ZnS ), cerussite (also called white lead ore) $\left(2 \mathrm{PbCO}_{3} \cdot \mathrm{~Pb}(\mathrm{OH})_{2}\right)$, malachite $\left(\mathrm{Cu}_{2}\left(\mathrm{CO}_{3} / \mathrm{OH}_{2}\right)\right)$, and azurite $\left(\mathrm{CuCO}_{3} \cdot \mathrm{Cu}(\mathrm{OH})_{2}\right)$ (see Table 7) (Rapp 2009; Peterson 2010). For the purposes of this study, these elements are evaluated in terms of "concentration spikes," which can be defined as a concentration of an element that is significantly over the "expected average." The expected average is determined based on the comparison of the readings taken from the rest of the vessel and the data gathered during the experimental phase of this study (Alberghina et al. 2012; Roberta et al. 2015). A common point of reference when determining relevant concentration spikes is the bottom of the vessel. Keeping in mind
that many pigments would have been considered prestige goods meant to be displayed, the bottoms of most vessels would have been less likely to have been decorated. This means that for most vessels, the bottom should provide a baseline composition of unaltered stone material, allowing for the assessment of how the chemical make-up on the rest of the vessel may have been altered. While this research criteria may be somewhat speculative, it is important to note that the majority of the artifacts selected for this study are carved from igneous stone in which a high concentration the targeted elements would be uncharacteristic. For instance, basalt does not usually contain significant amounts of lead, so unusually high concentration of lead may be used to suggest a lead-based pigment, such as cerussite.

All artifacts examined during this part of the project were analyzed in March of 2017 using a Thermo Scientific Niton XL3t Goldd+ pXRF. The instrument was set to the "Test All-GEO" mode and readings were allowed to cycle for 2 minutes per reading. There was a minimum of three readings taken per vessel with two being taken from opposing sides and one from the bottom. A fourth reading was taken for all cases in which the vessel was large enough to safely fit the muzzle of the pXRF into the interior of the vessel without risking damage. Additional readings were taken of particularly large vessels, or from any spot that seemed discolored, stained, or potentially pigmented. Points selected in this analysis were chosen to avoid any potential modern contamination caused by the application of artifact numbers, or other types of museum treatment.

### 3.4 PXRF RESULTS

The findings from the pXRF analysis help to shed light on the past presence of surface treatments, particularly in regards to the cocha and handled-bowl type vessels. Of the cocha type vessels, A3325 deserves particular attention. Because of its size, I took a total of five readings of this vessel: two from the interior, one from the bottom, and two from opposing sides. This vessel had no outward indication of previous surface treatment; however, when chemically analyzed, I found elevated levels of silver (Ag) coming from the interior surface. The levels of silver detected from the dead-center of the vessel measure to $18 \pm 7 \mathrm{ppm}$, and the silver content detected from a point halfway between the center of the vessel and the rim measure to $92 \pm 8 \mathrm{ppm}$. Additionally, Hg concentrations from the interior center ( $36 \pm 9$ ) and from the interior halfway point $(90 \pm 10)$ correspond with the concentrations of silver in a way that may be suggestive of a fire gilding process. While these readings may not appear significant in themselves, there were no detectable levels of silver from the readings taken on the outside of the vessel (Table 2). These exterior readings suggest that silver is not an innate component of the stone, which implies that the readings of silver detected from the interior surface of this vessel are in some way deviant, suggesting silver had been formerly applied to the surface. While the silver levels found on the interior may initially be interpreted as somewhat low, these numbers will be later reexamined in the discussion section of this paper.

Of the vessels studied, A3238 shows the most distinct chemical indicators of past surface treatment. Five readings were taken from this vessel, one from the interior, one from the bottom, two from opposing sides, and one targeting a distinctive patch of red staining thought to be the result of a surface treatment. When looking at the results from
the area of red staining, I observed a mercury $(\mathrm{Hg})$ concentration of $5095 \pm 57 \mathrm{ppm}$ and a sulfur level of ( $55124 \pm 533 \mathrm{ppm})$. By comparing the observed color of the staining to these high levels of mercury and sulfur, I have concluded that this staining is the result of a cinnabar (HgS) based surface treatment. As seen in Table 3, these readings are especially high when reviewing the readings taken from the other concentrations on the artifact, which did not show any discernable levels of mercury anywhere except for one reading taken from the side of the vessel, measuring to $157 \pm 12 \mathrm{ppm}$. Despite this area showing no visible mercury characteristics, this elevated reading likely shows that this area was pigmented in the past. Considering the expected geochemistry of the stone as indicated by the readings taken from the interior and bottom of this vessel, both which showed no detectable levels of mercury, this relatively small concentration of mercury suggests that this region of the vessel was previously pigmented with cinnabar and this surface treatment has been subsequently eroded. In addition to mercury and sulfur levels, it is worth examining iron levels, which could indicate the presence of a red ochre, one of the most popular red colorants used in the Andean world (Rapp, 2009). Based on the geochemistry displayed, however, we see that iron levels are consistent throughout the vessel and are in fact lowest in the pigmented spot (Table 3). This suggests that iron is likely innate to the vessel, and that the red material found on this vessel is not a red ochre.

Like A3238, I have identified A3309 as a 'handled-bowl' type vessel. A total of five readings were taken from this vessel: one from the interior, one from the bottom, two from opposing sides, and one targeting a distinctive patch of reddish brown, yellow, and black thought to be the results of a painted design. Based on the visual characteristics of the painted section, I expected a high presence of iron (Fe), which would be indicative of
ochre mineral pigments (Rapp 2009; Petersen 2010). After comparing the levels of iron in the painted area to the concentration of iron found on different parts of the vessel, however, I found that iron content within the painted area (79201 $\pm 631$ ) was within one standard deviation of the mean iron content of the vessel (80570), and thus cannot be considered statistically meaningful. Because the area that was painted was relatively small with multiple types of preserved pigment, the reading taken might represent an assemblage of pigment types rather than an isolated pigment, making it difficult to identify the pigments at this time. While I am currently unable to definitively identify the types of pigments used to decorate this vessel, it is worth noting that the painted area showed particularly high signs of lead ( $2622.04 \pm 42 \mathrm{ppm}$ ), copper ( $1058 \pm 38 \mathrm{ppm}$ ), and arsenic $(959 \pm 36 \mathrm{ppm})$ and notable levels of mercury ( $57 \pm 10$ ) and silver ( $41 \pm 5$ ). As exhibited on Table 4, these concentrations are considerably higher than those detected from anywhere else on the vessel. This may suggest a combination of the pigments realgar and cerussite.

After looking at the total collection, I observed an important theme regarding the concentrations of arsenic and lead across the entire collection. When looking at the total collection, I found that the bottoms of vessels tended to express higher levels of arsenic and lead than the sides and interiors of the same vessels. When looking at the bottoms of the vessels, 11 vessels showed extremely high concentrations of arsenic and 14 expressed high levels of lead. As shown on Table 8, most vessels that expressed high levels of lead also expressed a high level of arsenic, and a minority of these artifacts are "Teacup Mortar" type vessels despite this being the largest typological category. With these observations in mind, it seems likely that these readings represent a common storage
condition rather than a consistent treatment involved with the production of these goods.
In her 1996 study, Lisa Goldberg found that the Smithsonian Institute's National Museum of Natural History used a combination of arsenical and mercuric compounds to treat their collections for pests during the mid- $19^{\text {th }}$ century. It is possible that spikes in arsenic on the bottoms of many of these vessels may be the result of a similar practice. This is because vessels that have been sitting in collections for long enough may have ended up inadvertently absorbing the residual compounds used as pesticides that were left to accumulate on the shelves. This would also explain why the smaller teacup mortars were less likely to adopt these chemical profiles, as these goods would have generally been stored in drawers rather than left out on shelves. In a similar way, the detected levels of lead on the bottoms of these vessels may be the result of these vessels having sat on shelves that had been treated with lead-based paint.

### 3.5 EXPERIMENTAL STUDY

The intention of this aspect of the study is to gain a better understanding of what techniques the Inca may have implemented when decorating stone vessels and how these decorations would display chemically on the treated surface after the decorative material is removed. This is important, as many types of surface treatments may not preserve well due to natural erosional processes, the decay of pigments caused by light, or the intentional stripping of valuable metallic surface treatments by the Spanish or looters. This experiment was not to reconstruct all surface treatments employed by the Inca, but rather a small selection of some of the suspected treatments found over the course of this study. This can be considered a preliminary experiment that is intended to give me a general idea of how some surface treatments may chemically express post-removal.

To do this, I used 9 untreated, smoothed basalt stones to serve as proxies for Inca stone vessels. Basalt was specifically selected for this experiment due to its welldocumented use throughout Andean pre-history for building material, and for making grindstones, mortars, and bowls (Rapp 2009; Peterson 2010). Basalt was not only a commonly used material in the Inca world, but is also cheap and accessible today, making it an ideal fit for this study. Basalt is also a fine grained volcanic stone, and the material within a stone is usually chemically homogeneous, which means all pXRF readings to should be fairly consistent throughout the stone and not have anomalies that could skew my results.

After the basalt samples were procured, they were gently sanded, and each was marked with a sample number (E1-E9). Once the samples were prepared, each was weighted on a 0.01 g scale, and readings were then taken using an INNOV-X Model Delta Dynamic XRF DC-4000. Samples E2-E5 were marked with a line running down the middle and divided into side A and side B. Sample E1 was left blank over the course of the study in order to serve as a standard and detect for potential environmental contamination that might result from the preparation of the other samples. Four paints were then made, three were made by mixing pulverized cinnabar pigment with whipped egg whites, and one paint was made by mixing the cinnabar with pig blood. The three paints produced with egg whites were mixed to produce a light paint (1:10 emulsion), a medium paint (2:10 emulsion), and a heavy paint (3:10 emulsion). The paint made with pig blood was mixed using most of the remaining cinnabar pigment, resulting in a ratio of 1:4.

Samples E6 and E7 were both treated with multi-purpose gold leaf sheets. E6 was meant to reproduce a leafing technique, while E7 was meant to replicate a foiling technique. To achieve this, E6 was treated with alternating applications of egg whites and gold leaf sheets for a total of five layers of gold leaf sheet. For sample E7, I first heated the stone with a butane torch for about 1 minute, then applied a single gold leaf sheet, heated the sample again, and repeated the process until five gold leaf sheets had been applied. This proved to be more difficult than expected as the force of the butane torch was enough to displace the thin layers of gold leaf. This resulted in a dime-sized hole to erupt on the left side of the gold foiled surface. Despite this, gold layered on the right side of the sample seemed to have melded with the surface of the stone, which allowed for readings to be taken from the foiled surface. This can be seen in Figure 7.

Sample E8 was treated with unprocessed pig blood in order to examine how the metallics naturally present in blood may influence the interpretation of sample E5. The inclusion of sample E9 was not initially planned, but after the discovery of the inclusion of 10 sample sheets of silver leaf in the purchased gold leaf packet, I decided to prepare an additional sample. Because this sample was not initially planned, I did not have prepared basalt stone of the same source used for samples E1-E8. Instead, I used a similar type of basalt stone but of a different brand that I had purchased during a failed pilot of this experiment. During the failed trial, the stone that would become sample E9 was used as a standard, so it had not been subjected to any previous surface treatment. It should be noted that because E9 is a different brand of stone, it exhibits unique characteristics and will thus be treated separately when calculating the average weights and chemical composition between the stones. I treated this stone with the same techniques I
implemented with sample E7, in which I heated the stone with a butane torch, applied a single layer of silver sheet, heated the silver sheet, and repeated until 5 layers of silver sheet had been applied. The types of treatments associated with each sample and the relevant readings are presented in Table 6.

After surface treatment, all samples were then left to dry and/or settle for three and a half hours. Once the samples appeared completely dry, they were all weighed, and then a second coat was applied to the B side of samples E2-E5. All samples were then left to dry and/or settle for an additional three and a half hours and then all were weighed again. Then I took additional pXRF readings of each sample and sample side (when applicable) in order to measure the chemistry of the surface treatments. Once readings were completed, I abraded the surface of each sample with course sandpaper for approximately 30 seconds. After this, I measured the final weights of the samples, and took pXRF readings of each sample and sample side.

### 3.6 EXPERIMENTAL RESULTS

The data from this experiment reveals a number of key insights. First, by measuring the changes in weight, it is possible to gain an understanding of how uniform the application and removal processes were. Samples E2-E8 had an average weight of 218.75 g (sd=3.64) with a coefficient of variation (CV) $1.66 \%$. After both coats applied had dried, the average weight of the stones increased to 219.00 g ( $\mathrm{sd}=3.57 \mathrm{~g}$ ) with a CV of $1.63 \%$. This indicates that all surface treatments added an average of $0.25 \mathrm{~g}(\mathrm{sd}=0.076 \mathrm{~g})$ with a CV of $29.68 \%$. After the removal process, the average weight of the stones was
reduced to $218.761(\mathrm{sd}=3.63 \mathrm{~g})$ with a CV of $1.66 \%$, which indicates an average drop in weight of $0.24 \mathrm{~g}(\mathrm{sd}=0.072 \mathrm{~g})$ with a CV of $30.00 \%$.

By first comparing the CV calculated based on the weight of the stones before application (1.63\%), after application (1.63\%), and post-removal (1.66\%), and then examining the CV calculated based on the weight of the material gained (29.68\%) to the amount lost ( $30.00 \%$ ), it is possible to make two observations. First, it is clear that the average weight of the stones was minimally affected by the addition of surface treatments, implying that the surface treatment applied did not dominate the basalt sample. Second, and more importantly, these statistics suggest that amount of surface treatment added is statistically comparable to the amount removed. This is to say that while not all of the material added was removed, the amount removed was substantial.

After looking at the pXRF readings, the first thing I found is that all tested surface treatments appear to obstruct measurements of the underlying stone. I have concluded this after looking at the general trend of how rates of iron fluctuate across all samples during the experimental process. Before any surface treatment, iron was detected in an average concentration of $24146 \mathrm{ppm}(\mathrm{sd}=4070 \mathrm{ppm})$ with a CV of $17 \%$. After a surface treatment was applied, the average concentration of iron dropped to 11081 ppm (sd=4508ppm) with a CV of $41 \%$. Finally, when examining the samples after the materials were removed, I have found that the iron rates raise back to 23675 ppm (sd=4220ppm) with a CV of $18 \%$. What this shows is that the average rate of detected iron and titanium across all samples prior to surface treatment are more than halved once decorated; however, once the decorated surface is removed, the average rates return to close to those detected prior to the decorating process. These findings were particularly
surprising when considering sample E5 and E8, both of which were treated with the pig's blood binder. I had expected that the iron content of the blood itself would drastically increase the iron levels detected in the samples. Instead, what I found was that both E5 and E8 presented within a single standard deviation of the average for the dataset. While these numbers suggest that the decorated surface is shielding the host stone surface, it is important to note that the high CV value for the iron values show that there is considerable variability in how much each specific treatment actually masks the surface. This is significant as it addresses one of the considerations going into this study. As stated above, pXRF is most accurate with samples that are $>2 \mathrm{~mm}$ thick (Shackly 2011). While this is certainly true, there was an initial concern that a pXRF may primarily read the geochemistry of the host material, and not truly reflect elemental concentrations resulting from any surface treatment. What this data shows, however, is that when present, these surface patinas produced in this experiment were substantial enough to cause noticeable alterations to the detected elemental signatures.

Another finding that directly addresses the concerns involved with this study is that all the surface treatments tested for during the experiment left detectable elemental traces post-removal. The choice to use cinnabar, gold, and silver surface treatments for this experiment is due to the fact that each of these materials do not naturally occur in significant concentrations in basalt (along with being known to have been used by the Incas for decorating other items). For this reason, I will focus specifically on mercury, silver, and gold signatures. When looking at the readings taken from the bare stone samples, the mercury contents detected in the stone were negligible, with the highest mercury content detected amongst all samples being $8 \pm 3 \mathrm{ppm}$. After the application of the
cinnabar emulsions, there are not only discernable concentrations of Hg , but as seen on Table 6, these concentrations echo specific preparation styles. Measurements taken from these same vessels once the materials were removed showed clear evidence of the past presence of mercury, with the lowest reading coming from E2 Side B which showed a mercury concentration of $608 \pm 9 \mathrm{ppm}$. Curiously, the highest mercury reading from the post-removal dataset also came from E2 Side A (2277 $\pm 20$ ). As seen on the post-removal section of Table 6 , readings taken from the post-removal phase show a much more complicated relationship, and do not mirror the preparation patterns of the samples.

When looking at the samples treated with metallic sheet, I observed a similar trend to those treated with the cinnabar egg white emulsion, in which there was virtually no silver or gold detected prior to application, a substantial increase while decorated, and a marked decrease post-removal. Despite the steep decrease observed in the post-removal phase, there were still discernable metallic concentrations among all three samples. As displayed on Table 6, when looking at samples E6 and E7, sample E6 displayed higher concentrations of gold during both the decoration phase, and in the post-removal phase. This seems to imply that the leafing technique implemented was more successful in producing a firm bond with the host basalt stone than the foiling technique. Admittedly, this may not be an accurate reflection of the difference between how these techniques produce chemical imprints in their host material but may instead reflect my own ineptness in gold gilding. Regardless, the data produced by this experiment indicates that stone materials are capable of retaining metal and pigment surface treatments in a quantity that can be detected by pXRF after these materials have been stripped.

One important consideration that needs to be addressed is the manner in which the surface treatments were removed. The mechanical abrasion I used to remove the surface treatment on the samples does not accurately represent any natural erosional process that may affect archaeological samples. While this treatment may resemble the reckless manner in which precious goods were stripped from stone materials by the Spanish invaders, they would have likely scrapped gold and silver materials of a surface rather than ground it way. This is of concern when considering that while grinding the surface treatments off the material, I may have inadvertently been working the materials into the surface of the stone by pushing and grinding the samples with the sandpaper. Future studies may benefit by avoiding this technique.

## CHAPTER 4: DISCUSSION

As stated previously, a central issue I hope to remedy is that there has been an unfortunate lack of work dedicated to stone vessels in the past. As such, the goal of this project is to elucidate how the many styles and decorative strategies displayed in Inca stone vessels can inform the status and use of these vessels. In this section, I will first review the main points to be taken from the typology, pXRF lab analysis, and the experimental study. After this, I will show how the findings from these three sections relate to one another and enrich our understanding of Inca stone vessels. Finally, I will analyze what these findings say about the status of these goods and how this helps inform our understanding of how these artifacts were used by the Inca peoples.

The purpose of the typology I have established over the course of this study is meant to expand the way we view stone vessels. As explained above, past studies have treated stone vessels as mortars designed for utility and neglected the possibility that these were ritually significant goods imbued with religious significance. This is not to imply that ritual goods and utility goods are mutually exclusive categories but meant to show that we can greatly expand our understanding of these goods by considering their social significance. This is most clear when examining the structural differences between cochas, teacup mortars, and handled-bowls.

As discussed above, the most unique features of cocha-style vessels are their large circular bodies, horizontal lips, and shallow, flat interior basins. These qualities would likely make it difficult to grind and extract materials, especially considering that not all vessels of this style include handles. This is not the case for teacup mortars, whose generally deep, concave interior would have produced an ideal surface for pulverizing
and grinding. Considering the presence of interior stains and the lack of exterior decorations, it seems clear that this vessel type was likely valued as a utility good. Handled-bowls, however, seem to fill the gap between cochas and teacup mortars, as they were highly stylized, implying they were meant to be exhibited, and included an interior surface that could be used for processing and/or serving. In this way, these three types of goods express a range of prestige and use.

The inferences I have made about these vessels by examining their form are supported by the findings of the pXRF lab analysis. Of note are vessels A3325 and A3238. A3325 is significant as it is the only cocha-style vessel included in this study that chemically expressed any indication of previous surface treatment. This vessel exhibited silver in the center of the interior of the vessel and from the periphery of the interior of the vessel. While the levels of silver detected were relatively low, there were no detectable traces of silver anywhere on the exterior of the vessel, implying that these readings are not reflective of the innate geochemistry of the stone material. Furthermore, mercury concentrations from the interior of the vessel seem to be elevated when compared to the readings taken from the bottom and side of the vessel. The combination of silver and mercury readings suggest that the interior of this vessel may have been once been fire gilded with silver foil (Oddy et al. 2012). It seems likely that this vessel was decorated with silver rather than used as a surface to work silver when considering that working metal is a generally rough process that would likely affect the entirety of the vessel and leave distinctive visible signs of pounding, grinding, and shaping metal (Grossman 1972; Temme 1994). Furthermore, this utilitarian interpretation of this vessel does not explain the presence of mercury detected in the sample.

While three of the handled-bowls exhibited direct or indirect evidence of a surface treatment, A3238 was the only one in which it was possible to directly identify the pigment. As discussed above, by comparing the levels of mercury to iron, it seems clear that the red pigment observed on the surface of this vessel was cinnabar and not a red ochre, or a cinnabar and red ochre blend (see Table 3). Both the archaeological record and ethnohistoric reports show that cinnabar was a particularly valuable pigment in the Inca world with limited social accessibility (Cobo 1990 [1653]; Siracusano 2005; Garcilaso de la Vega 2006 [1609]; Rapp 2009; Peterson 2010; Suarez 2016). Additionally, the color red is reported by chroniclers such as Cobo (1990 [1653]) to have important religious significance. This indicates that while this vessel could have been and likely was - used for practical purposes, it was also a religiously significant good that was presumably used in a specific, deliberate way that involved ceremony.

Another substantial finding from this portion of the project is that elevated levels of arsenic and lead concentrated on the bottoms of the vessels. These findings are particularly interesting because they show evidence for modern contamination stemming from past preservation treatments. While these practices have long since abandoned, this shows that this treatment of collections has left a lasting chemical imprint on the stone vessels, and that people working with such vessels should take precautions when handling these items.

While the pXRF lab results provided key insights into the decorative materials and strategies associated with these vessels, the experimental study allows for a comparative basis so that these readings can be properly understood. The most important finding from the experimental study was that all surface treatments tested for displayed
discernable elemental signatures. What this tells us is that pXRF is not only capable of detecting surface treatments after they have been either forcibly removed or naturally eroded, but that in some cases, it is capable of identifying specific types of surface treatments.

After reviewing the form and decorative styles observed in this collection, I propose that cochas were most likely used as a ritual basin for holding water and/or other liquids. This interpretation is supported by the recurrent serpent iconography found on both the cocha-style vessels I studied and those documented by Burger and Salazar (2004). As stated previously, past scholars and ethnohistorians noted the symbolic association between serpents and water made by the past Andean peoples. It has been well-documented that water was a symbolically significant good which was often incorporated into administrative and ritual displays (Cobo 1990 [1653]; Glowacki and Malpass 2003; Bray; 2013). Considering the ritual significance of water, it seems likely that there would have been specific objects meant to hold, display, and/or serve water. The diversity in types of rituals that could have necessitated the use of water bearing cochas may explain the assorted decorative styles seen in these vessels. Since the use and offering of water was fairly common in the Andean world, certain designs, material, and decorative styles may have been a way to specifically associate a given cocha with a specific ceremony.

Regardless of whether one accepts this particular interpretation of cocha-style vessels, there is still a lot to be said about the way highly decorated stone vessels can and should be treated within the archaeological record. As previously stated, careful examinations of high status goods such as textiles and ceremonial drinking vessels have
offered valuable insights into ideas of gender, regional identity, and social rank in the Andean world. Much in the same way, the evidence here shows that stone vessels are symbolically saturated with many of the same types of cultural significance but are still yet to be thoroughly deciphered.

Over the course of my study, I have observed that many of the elaborate and decorated styles of vessel were made from a variety of vibrant, multi-colored stone materials. These same vessels are also often finely crafted and carved with elaborate iconographic motifs. Those that were made from less vivid materials were occasionally decorated with rare, socially restricted materials such as cinnabar and other unidentified pigments. This set of qualities all suggest that these goods were meant to be presented, appreciated, and revered as spectacular goods. The lionization of these goods is evident when considering on the additional measures implemented for presenting these goods.

Over the course of this study, I have found that of the 30 items sampled 2 displayed demonstrable evidence of the use of pigment(s) and 1 showed evidence of metal. Both vessel A3238 and A3309 had pigment(s) added to their exterior surfaces which means it would have been visible to those viewing these goods from a distance, as well as to those directly engaged with potential ritual processions. This would have not only been a way of amplifying the perceived value of these goods, but possibly a way of associating these goods with specific rites or deities. Vessel A3325 was the only good examined that showed evidence for the past presence of metal, which is suggested by two pXRF readings taken from the interior surface of the good that showed characteristically high levels of silver. Based on the form, associated motifs, and pXRF readings, it seems like this vessel and possibly other vessels of this type were somehow associated with
water and likely used in a ritualistic way. While highly stylized stone vessels would likely have been valued in and of themselves, the extra considerations exhibited through the use of additive decorative materials shows that these goods played a substantial role in pre-Hispanic Andean culture.

## CHAPTER 5: CONCLUSION

The goal of this project has been to expand the way we perceive and treat stone vessels in the archaeological record. While it has been suggested that cochas and handled-bowls were used as mortars, there is a clear and significant distinction to be made based on whether a vessel was intended to be displayed. This is to say that while stone vessels were likely valued for their durability and functionality, the careful way that some of these goods were prepared shows that these items were more than just utilitarian - they were precious ritual goods intended to signal prestige. The labor investment and artisanship required to source, carve, and polish vessels like cochas and handled-bowls indicates that these goods would have likely played a special role in Inca society. Decorating these goods even further by bedecking them with metals and pigments would amplified the prestige of these goods because of the inherent value of these goods and their ability to impart symbolic significance. While the exact concepts that these goods were meant to portray may be difficult to ascertain, the more work done dedicated to expanding and elaborating our understanding of both pigments and stone vessels will indefinitely lead to a better understanding of Inca ritual and religion.

The more work dedicated to understanding how stone vessels were being produced and how the materials used to finish these goods were sourced and processed could lead to important insights into Inca daily life and culture. This is because prestige goods represent more than just the final product, but a constituent of tasks required to produce pieces intended for reverence. Stone vessels are a unique and rich source of information that can be studied in a multitude of fashions, including iconographic depictions, material sourcing and preference, and surface treatments. By better
understanding what these details signify, we can better understand how these qualities were meant to transmit complex notions of identity and prestige.

Throughout this study, I have shown substantial results in regards to how these vessel were produced, there is still a considerable amount of research that could elucidate how this artifact type may have been used and perceived in the past. The typology I have established is only meant to be a foothold in a much larger frame of the type of stone vessels that were produced by the Inca. Furthermore, there is considerable information that may be garnered through ethnographic research dedicated to how similar vessels may be used by peoples living today. By expanding our vocabulary, repertoire, and understanding of stone vessels, we can gain a more nuanced understanding of the past peoples of the Andes.
